TOPOLOGY

ABSTRACT

The rapid growth in the volume, variety, and dimensionality of available data has made identifying, extracting, and exploiting its underlying structure a central challenge in data analysis and statistical learning. Topological data analysis (TDA) is a recent and rapidly developing field that provides topological and geometric tools for identifying relevant features in potentially complex data. It offers mathematically rigorous theories and computational methods that can be used independently or in conjunction with other data-analysis and statistical-learning techniques. This article provides nonexperts with a concise introduction to selected fundamental and practical aspects of TDA. (Bonis, n.d.) (Sale, n.d.) (Fasy et al., 2021)

Introduction and Motivation

Topological data analysis (TDA) is a relatively recent field that emerged from research in applied algebraic topology and computational geometry during the first decade of this century. Although geometric approaches to data analysis have a much longer history, TDA was established as a distinct field through pioneering work on persistent homology (Yen & Cheong, 2021), and was subsequently popularized by the landmark article of Carlsson (2009). TDA is motivated primarily by the premise that topology and geometry provide powerful means of inferring robust qualitative and, in some cases, quantitative information about the structure of data. (Yen & Cheong, 2021)

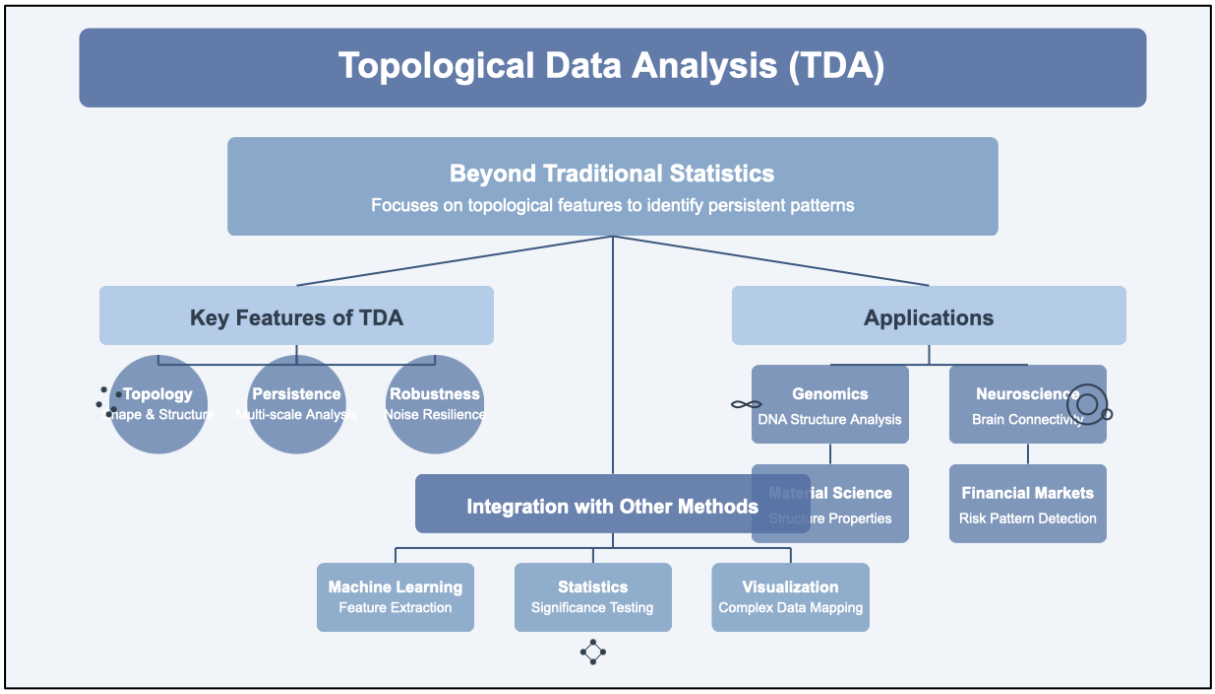

TDA seeks to provide mathematically rigorous statistical and algorithmic methods for inferring, analyzing, and exploiting the complex topological and geometric structures underlying data, which are often represented as point clouds in Euclidean or more general metric spaces. In recent years, substantial effort has been devoted to developing robust and efficient data structures and algorithms for TDA. These methods are now implemented in accessible standard libraries, including the GUDHI library (C++ and Python), Maria et al. (2014), its R interface, Fasy et al. (2014a), Dionysus, PHAT, DIPHA, and Giotto. Although the field continues to evolve, TDA now offers mature and efficient

tools that can be used alongside or in conjunction with other data-science methods (Thabane & Akhtar-Danesh, 2008).

The Topological Data Analysis Pipeline

TDA

Has recently known developments in various directions and application fields. There now exist a large variety of methods inspired by topological and geometric approaches.

Providing a complete overview of all these existing approaches is beyond the scope of this introductory survey. However, many standard ones rely on the following basic pipeline that will serve as the backbone of this article: (Garlick, 2020)

- The input is assumed to be a finite set of points coming with a notion of distance—or similarity—between them. This distance can be induced by the metric in the ambient space (e.g., the Euclidean metric when the data are embedded in $\mathbb{R}^d$) or comes as an intrinsic metric defined by a pairwise distance matrix. The definition of the metric on the data is usually given as an input or guided by the application. It is, however, important to notice that the choice of the metric may be (Alexander, 2026)critical to revealing interesting topological and geometric features of the data.

- A “continuous” shape is built on the top of the data in order to highlight the underlying topology or geometry. This is often a simplicial complex or a nested family of simplicial complexes, called a filtration, which reflects the structure of the data on different scales. Simplicial complexes can be seen as higher-dimensional generalizations of neighboring graphs that are classically built on the top of data in many standard data analysis or learning algorithms. The challenge here is to define such structures as are proven to reflect relevant information about the structure of data and that can be effectively constructed and manipulated in practice. (De Gruyter, 2022)

- Topological or geometric information is extracted from the structures built on the top of the data. This may either result in a full reconstruction, typically a triangulation, of the shape underlying the data from which topological/geometric features can be easily extracted or in crude summaries or approximations from which the extraction of relevant information requires specific methods, such as persistent homology. Beyond the identification of interesting topological/geometric information and its visualization and interpretation, the challenge at this step is to show its relevance, in particular its stability with respect to perturbations or the presence of noise in the input data. For that purpose, understanding the statistical behavior of the inferred features is also an important question. (Wiley, 2019)

- The extracted topological and geometric information provides new families of features and descriptors of the data. They can be used to better understand the data—in particular, through visualization—or they can be combined with other kinds of features for further analysis and machine learning tasks. This information can also be used to design well-suited data analysis and machine learning models. Showing the added value and the complementarity (with respect to other features) of the information provided using (PeerJ, n.d.)

TDA tools is an important question at this step.

Topological Data Analysis and Statistics

Until quite recently, the theoretical aspects of TDA and topological inference mostly relied on deterministic approaches. These deterministic approaches do not take into account the random nature of data and the intrinsic variability of the topological quantity they infer. Consequently, most of the corresponding methods remain exploratory, without being able to efficiently distinguish between information and what is sometimes called the "topological noise". (Routledge-Cavendish, 2012)

A statistical approach to TDA means that we consider data as generated from an unknown distribution but also that the topological features inferred using TDA methods are seen as estimators of topological quantities describing an underlying object. Under this approach, the unknown object usually corresponds to the support of the data distribution (or part of it). The main goals of a statistical approach to topological data analysis can be summarized as the following list of problems: (Fasy et al., 2021)

- **Topic 1:** proving consistency and studying the convergence rates of TDA methods.
- **Topic 2:** providing confidence regions for topological features and discussing the significance of the estimated topological quantities.
- **Topic 3:** selecting relevant scales on which the topological phenomenon should be considered, as a function of observed data.
- **Topic 4:** dealing with outliers and providing robust methods for TDA. (Byrne et al., 2022)

Applications of Topological Data Analysis in Data Science

On the application side, many recent promising and successful results have demonstrated the interest in topological and geometric approaches in an increasing number of fields such as material science (Kramar et al., 2013; Nakamura et al., 2015; Pike et al., 2020), 3D shape analysis (Skraba et al., 2010; Turner et al., 2014b), image analysis (Qaiser et al., 2019; Rieck et al., 2020), multivariate time series analysis (Khasawneh and Munch, 2016; Seversky et al., 2016; Umeda, 2017), medicine (Dindin et al., 2020), biology (Yao et al., 2009), genomics (Carrière and Rabadán, 2020), chemistry

(Lee et al., 2017; Smith et al., 2021), sensor networks De Silva and Ghrist (2007), or transportation (Li et al., 2019), to name a few. It is beyond our scope to give an exhaustive list of applications of TDA. On the other hand, most of the successes of TDA result from its combination with other analysis or learning techniques for a discussion and references). So, clarifying the position and complementarity of TDA with respect to other approaches and tools in data science is also an important question and an active research domain. (SAGE Publications, Inc., 2011)

Other reviews on TDA can be found in the literature, which are complementary to our work. Wasserman (2018) presented a statistical view on TDA, and it focused, in particular, on the connections between TDA and density clustering. Sizemore et al. (2019) proposed a survey about the application of TDA to neurosciences. Finally, Hensel et al. (2021) proposed a recent overview of applications of TDA to machine learning.

Metric Spaces, Covers, and Simplicial Complexes

As topological and geometric features are usually associated with continuous spaces, data represented as finite sets of observations do not directly reveal any topological information *per se*. A natural way to highlight some topological structure out of data is to "connect" data points that are close to each other in order to exhibit a global continuous shape underlying the data. Quantifying the notion of closeness between data points is usually done using a distance (or a dissimilarity measure), and it often turns out to be convenient in TDA to consider data sets as discrete metric spaces or as samples of metric spaces. (Frosini, 2021)This section introduces general concepts for geometric and topological inference; a more complete presentation of the topic is given in the study by Boissonnat et al. (2018).

The union of the simplices of K is a subset of $\mathbb{R}^d$called the underlying space of K that inherits from the topology of $\mathbb{R}^d$. So, K can also be seen as a topological space through its underlying space. Notice that once its vertices are known, K is fully characterized by the combinatorial description of a collection of simplices satisfying some incidence rules. (Shi et al., 1996)

Given a set *V*, an abstract simplicial complex with the vertex set *V* is a set $\widetilde{K}$ of finite subsets of *V* such that the elements of *V* belong to $\widetilde{K}$ and for any $\sigma \in \widetilde{K}$, any subset of σ belongs to $\widetilde{K}$. The elements of $\widetilde{K}$ are called the faces or the simplices of $\widetilde{K}$. The dimension of an abstract simplex is just its cardinality minus 1 and the dimension of $\widetilde{K}$ is the largest dimension of its simplices. Notice that simplicial complexes of dimension 1 are graphs (Nenashev, 1991).

The combinatorial description of any geometric simplicial *K* obviously gives rise to an abstract simplicial complex $\widetilde{K}$. The converse is also true; one can always associate with an abstract simplicial complex $\widetilde{K}$ a topological space $\left|\widetilde{K}\right|$ such that if *K* is a geometric complex whose combinatorial description is the same as $\widetilde{K}$, the underlying space of *K* is homeomorphic to $\left|\widetilde{K}\right|$. Such a *K* is called a geometric realization of $\widetilde{K}$. As a consequence, abstract simplicial complexes can be seen as topological spaces and geometric complexes can be seen as geometric realizations of their underlying combinatorial structure. So, one can consider simplicial complexes at the same time as combinatorial objects that are well suited for effective computations and as topological spaces from which topological properties can be inferred. (Cambridge University Press, n.d.)

Statistic for a Family of Persistent Diagrams or Other Representations

Up to now in this section, we were only considering statistics based on one single observed persistence diagram. We now consider a new framework where several persistence diagrams (or other representations) are available, and we are interested in providing the central tendency, confidence regions, and hypothesis tests for topological descriptors built on this family. (Edwards, 2019)

Central Tendency for Persistent Homology

Mean and Expectations of Distributions of Diagrams

The space of persistence diagrams being a general metric space but not a Hilbert space, the definition of a mean persistence diagram is not obvious and unique. One first natural approach to defining a central tendency in this context is to consider Fréchet means of distributions of diagrams. (Mitra & Virk, 2021)Their existence has been proven in the study by Mileyko et al. (2011), and they have also been characterized in the study by

Turner et al. (2014a). However, they may not be unique, and they turn out to be difficult to compute in practice. To partly overcome these problems, different approaches have been recently proposed based on numerical optimal transport Lacombe et al. (2018) or linear representations and kernel-based methods Divol and Chazal (2020).

Topological Signatures from Subsamples

Central tendency properties of persistent homology can also be used to compute topological signatures for very large data sets, as an alternative approach to overcome the prohibitive cost of persistence computations. Given a large point cloud, the idea is to extract many subsamples, to compute the persistence landscape for each subsample, and then to combine the information (Kong & Fan, 2023).

For any positive integer m, let X = {x_1, … , x_m} be a sample of m points drawn from a measure μ in a metric space M and which support is denoted by $\mathbb{X}_\mu$. We assume that the diameter of $\mathbb{X}_\mu$is finite and upper bounded by $\frac{T}{2}$, where T is the same constant as in the definition of persistence landscapes in. For ease of exposition, we focus on the case k = 1 and the set λ(t) = λ(1, t). However, the results we present in this section hold for k > 1 (Chapman and Hall/CRC, 2003). The corresponding persistence landscape (associated with the persistence diagram of the Čech or Rips–Vietoris filtration) is λ_X and we denote by $\Psi_\mu^m$the measure induced by $\mu^{\otimes m}$ on the space of persistence landscapes. Note that the persistence landscape λ_X can be seen as a single draw from the measure Ψ_μ^m. The point-wise expectations of the (random) persistence landscape under this measure is defined by $\mathbb{E}_{\Psi_\mu^m}[\lambda_X(t)], t \in [0, T]$. The average landscape $\mathbb{E}_{\Psi_\mu^m}[\lambda_X]$has a natural empirical counterpart, which can be used as its unbiased estimator. Let $S_1^m, \ldots, S_\ell^m$be ℓ independent samples of size m from $\mu^{\otimes m}$. We define the empirical average landscape as

$$\lambda_\ell^{\bar{m}}(t) = \frac{1}{b}\sum_{i=1}^{b} \lambda_{S_i^m}(t), \text{ for all } t \in [0, T],$$

$\lambda_\ell^{\bar{m}}$to estimate $\lambda_{\mathbb{X}_\mu}$. Note that computing the persistent homology of $\mathbb{X}_n$is O(exp(n)), whereas computing the average landscape is O(b exp(m)).

Another motivation for this subsampling approach is that it can also be applied when μ is a discrete measure with the support $\mathbb{X}_N = \{x_1, \ldots, x_N\}$lying in a metric space M. This

framework can be very common in practice, when a continuous (but unknown) measure is approximated by a discrete uniform measure μ_N on $\mathbb{X}_N$.

The average landscape $\mathbb{E}_{\Psi_\mu^m}[\lambda_X]$is an interesting quantity on its own, since it carries some stable topological information about the underlying measure μ, from which the data are generated.

[Chazal et al. (2015a)] Let $X \sim \mu^{\otimes m}$and $Y \sim \nu^{\otimes m}$, where μ and ν are two probability measures on M. For any $p \geq 1$, we have (Chapman and Hall/CRC, 2003)

$$\left\| \mathbb{E}_{\Psi_\mu^m}[\lambda_X] - \mathbb{E}_{\Psi_\nu^m}[\lambda_Y] \right\|_\infty \leq 2\, m^{\frac{1}{p}} W_p(\mu, \nu),$$

Chazal et al. (2015b), Chazal et al. (2015c), following this strategy, confidence bands for landscapes are proposed from the observation of landscapes $\lambda_1, \ldots, \lambda_N$ drawn i. i. d. from a random distribution in the space of landscapes. The asymptotic validity and the uniform convergence of the multiplier bootstrap is shown in this framework. Note that similar results can also be proposed for many representations of persistence, in particular by showing that the corresponding functional spaces are Donsker spaces. (Johnson, 2023)

Other Statistical Approaches to Topological Data Analysis

Statistical approaches for TDA are seeing an increasing interest and many others have been proposed in recent years or are still subject to active research activities, as illustrated in the following non-exhaustive list of examples. (Johnson, 2023)

Hypothesis Testing

Several methods have been proposed for hypothesis testing procedures for persistent homology, mostly based on permutation strategies and for two-sample testing. Robinson and Turner (2017) focused on pairwise distances of persistence diagrams, whereas Berry et al. (2020) studied more general functional summaries. Hypothesis tests based on kernel approaches have been proposed in the study by Kusano (2019). A two-stage hypothesis test of filtering and testing for persistent images was also presented in the study by Moon and Lazar (2020). (Copernicus GmbH, 2019)

Persistence Homology Transform

The representations introduced before are all transformations derived from the persistence diagram computed from a fixed filtration built over a data set. The persistence homology transform introduced in the studies by Curry et al. (2018), Turner et al. (2014b) to study shapes in $\mathbb{R}^d$takes a different path by looking at the persistence homology of the sublevel set filtration induced by the projection of the considered shape in each direction in $\mathbb{R}^d$. It comes with several interesting properties; in particular, the persistence homology transform is a sufficient statistic for distributions defined on the set of geometric and finite simplicial complexes embedded in $\mathbb{R}^d$. (Copernicus GmbH, 2019)

Bayesian Statistics for Topological Data Analysis

A Bayesian approach to persistence diagram inference has been proposed in the study by Maroulas et al. (2020) by viewing a persistence diagram as a sample from a point process. This Bayesian method computes the point process posterior intensity based on a Gaussian mixture intensity for the prior. (Nasrin et al., 2024)

Persistent Homology and Machine Learning

Using TDA, particularly persistent homology, in machine learning has prompted intense research. Although recent advances are beyond this article's scope, we briefly outline the main directions and provide references to help newcomers get started. (Immonen et al., 2023)

Topological Data Analysis for Exploratory Data Analysis and Descriptive Statistics

In some domains, TDA is a valuable tool for exploratory analysis and visualization. For example, the Mapper algorithm offers a powerful means of investigating and visualizing the global topological structure of complex data sets. In certain cases, persistence diagrams derived from data can be interpreted directly and used to deepen our understanding of the phenomena that generated the data. Examples include the study of force fields in granular media (Kramar et al., 2013), atomic structures in glass (Nakamura

et al., 2015), the evolution of convection patterns in fluid dynamics (Kramár et al., 2016), machining monitoring (Khasawneh and Munch, 2016), and nanoporous structures in chemistry (Lee et al., 2017). In these applications, topological features can be clearly related to specific geometric structures and patterns in the data. (Pietrobon et al., 2025)

Persistent Homology for Feature Engineering

There are many other cases where persistence features cannot be easily or directly interpreted but present valuable information for further processing. However, the highly nonlinear nature of diagrams prevents them from being immediately used as standard features in machine learning algorithms. (Hacquard, n.d.) (Hacquard, n.d.)

Persistence landscapes and linear representations of persistence diagrams offer a first option to convert persistence diagrams into elements of a vector space that can be directly used as features in classical machine learning pipelines. This approach has been used, for example, for protein binding (Kovacev-Nikolic et al., 2016), object recognition (Li et al., 2014), or time series analysis. In the same vein, the construction of kernels for persistence diagrams that preserve their stability properties has recently attracted some attention. Most of them have been obtained by considering diagrams as discrete measures in $\mathbb{R}^2$. Convolving a symmetrized (with respect to the diagonal) version of persistence diagrams with a 2D Gaussian distribution, Reininghaus et al. (2015) introduced a multiscale kernel and applied it to shape classification and texture recognition problems. (Hacquard, n.d.)Considering the Wasserstein distance between projections of persistence diagrams on lines, Carriere et al. (2017) built another kernel and tested its performance on several benchmarks. Other kernels, still obtained by considering persistence diagrams as measures, have also been proposed in the study by Kusano et al. (2017).

Various other vector summaries of persistence diagrams have been proposed and then used as features for different problems. For example, basic summaries were considered in the study by Bonis et al. (2016) and combined with quantization and pooling methods to address nonrigid shape analysis problems; Betti curves extracted from persistence diagrams were used with one-dimensional convolutional neural networks (CNNs) to analyze time-dependent data and recognize human activities from inertial sensors in the

studies by Dindin et al. (2020), Umeda (2017); persistence images were introduced in the study by Adams et al. (2017) and were considered to address some inverse problems using linear machine learning models in the study by Obayashi et al. (2018). (3 LEGAL EDUCATION, 2012) (eLife Sciences Publications, Ltd, n.d.)

The kernels and vector summaries of persistence diagrams mentioned above are built independently of the considered data analysis or learning task. Moreover, it appears that in many cases, the relevant topological information is not carried by the whole persistence diagram but is concentrated in some localized regions that may not be obvious to identify. This usually makes the choice of a relevant kernel or vector summary very difficult for the user. (Islambekov & Luchinsky, 2025)To overcome this issue, various authors have proposed learning approaches that allow us to learn the relevant topological features for a given task. In this direction, Hofer et al. (2017) proposed a deep learning approach to learn the parameters of persistence image representations of persistence diagrams, while Kim et al. (2020) introduced a neural network layer for persistence landscapes. In the study by Carrière et al. (2020a), the authors introduced a general neural network layer for persistence diagrams that can be either used to learn an appropriate vectorization or directly integrated in a deep neural network architecture. Other methods, inspired from *k*-means, propose unsupervised methods to vectorize persistence diagrams (Royer et al., 2021; Zieliński et al., 2010), some of them coming with theoretical guarantees (Chazal et al., 2020). (much information will, 2012) (PeerJ, n.d.)

Persistent Homology for Machine Learning Architecture Optimization and Model Selection

More recently, TDA has seen new developments in machine learning where persistent homology is no longer used for feature engineering but as a tool to design, improve, or select models. (Hacquard, n.d.) (abilities monitor much, 2005) Many of these tools rely on the introduction of loss or regularization functions depending on persistent homology features, raising the problem of their optimization. Building on the powerful tools provided by software libraries such as PyTorch or TensorFlow, practical methods allowing us to encode and optimize a large family of persistence-based functions have been proposed and experimented on). (SAGE Publications, 2012)A general framework for

persistence-based function optimization based on stochastic subgradient descent algorithms with convergence guarantees has been recently proposed and implemented in an easy-to-use software tool (Islambekov & Luchinsky, 2025). With a different perspective, another theoretical framework to study the differentiable structure of functions of persistence diagrams has been proposed in the study by (Achord, 1992 (PeerJ, n.d.)) . (Table 6: Combined, n.d.)

Figure 1: Seeing Shapes in Data

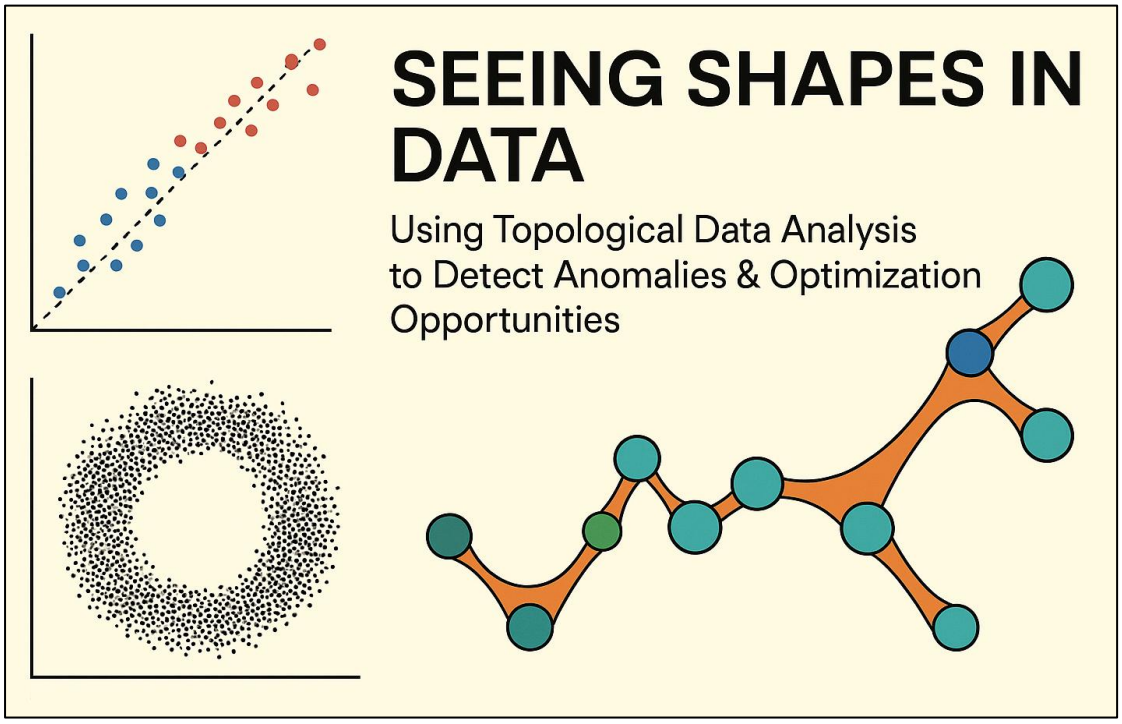

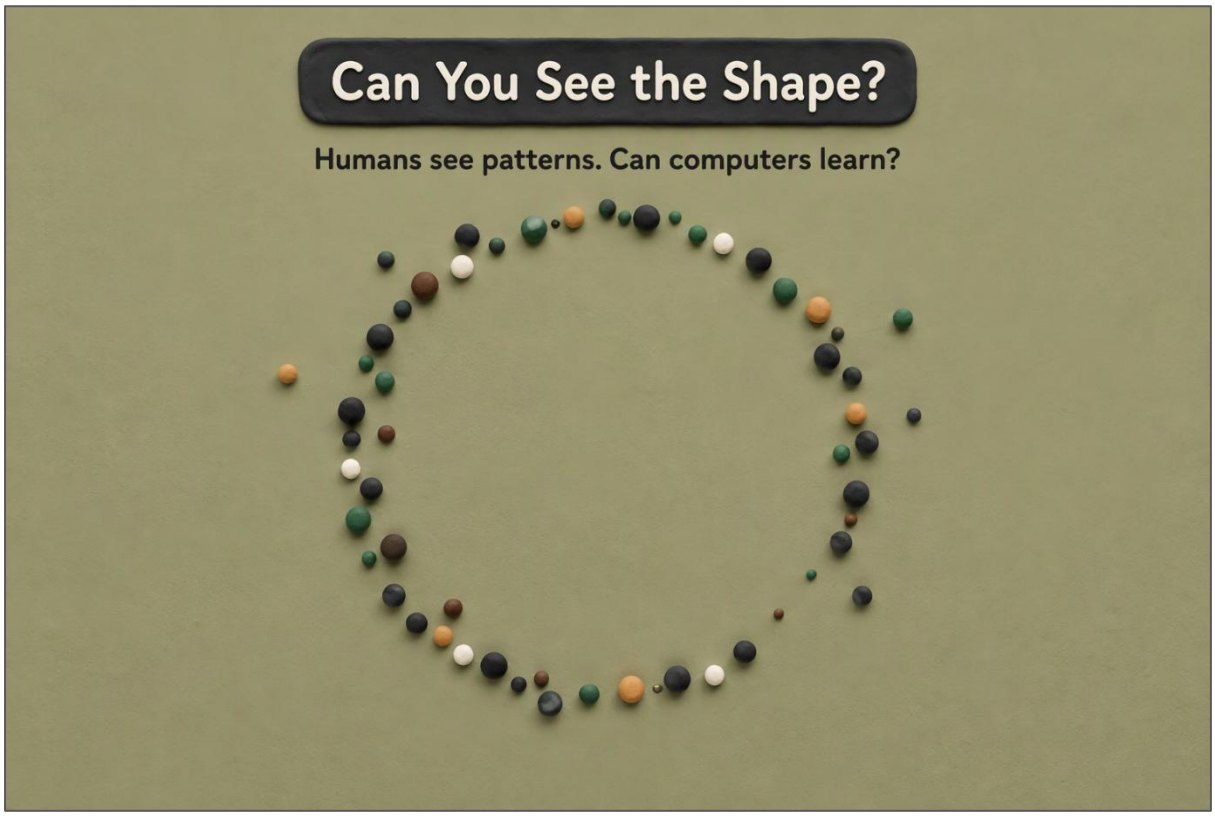

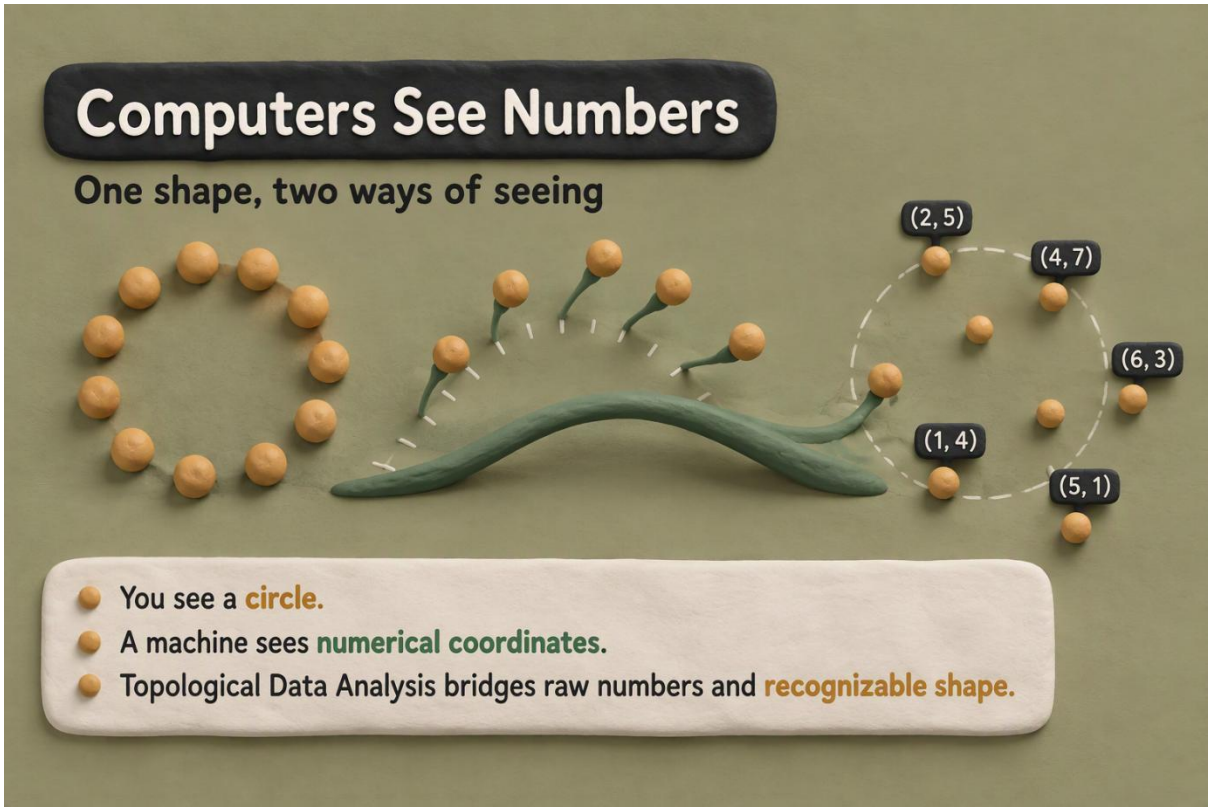

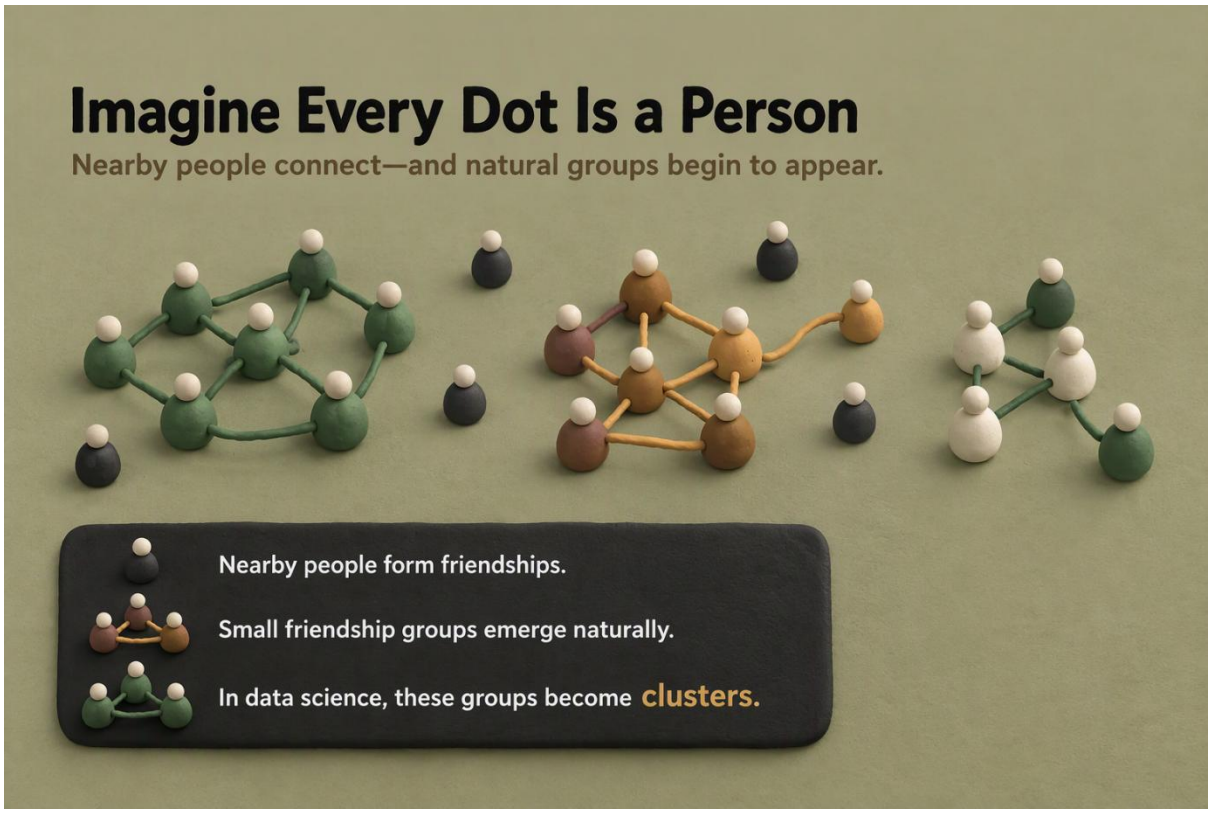

Figure 2-10: The flow of TDA Visualized in Human Terminology

Computers See Numbers
One shape, two ways of seeing
(2, 5)
(4, 7)
(6, 3)
(1, 4)
(5, 1)
You see a circle.
A machine sees numerical coordinates.
Topological Data Analysis bridges raw numbers and recognizable shape.

Imagine Every Dot Is a Person
Nearby people connect—and natural groups begin to appear.
Nearby people form friendships.
Small friendship groups emerge naturally.
In data science, these groups become clusters.

Growing Around Each Data Point

Expanding neighborhoods turn proximity into structure.

PLACE

GROW

CONNECT

Place a bubble around every point.

Grow all bubbles together.

Overlaps create connections—and reveal **hidden structure.**

The Shape Emerges

Connections turn scattered points into a visible pattern.

- Individual points become a network.
- Larger patterns begin to emerge.
- The connections reveal a hidden loop.

Topology Studies Holes

Shape can change. Holes cannot.

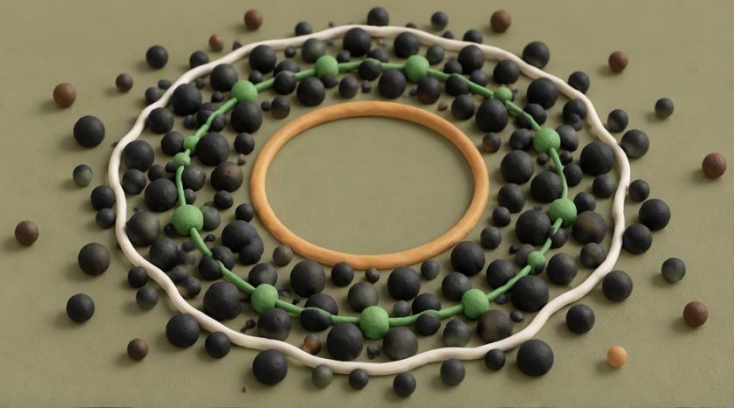

DOUGHNUT — ONE HOLE

BALL — ZERO HOLES

Topology ignores size, color, and material—
it asks how many holes an object has.

The Hidden Hole

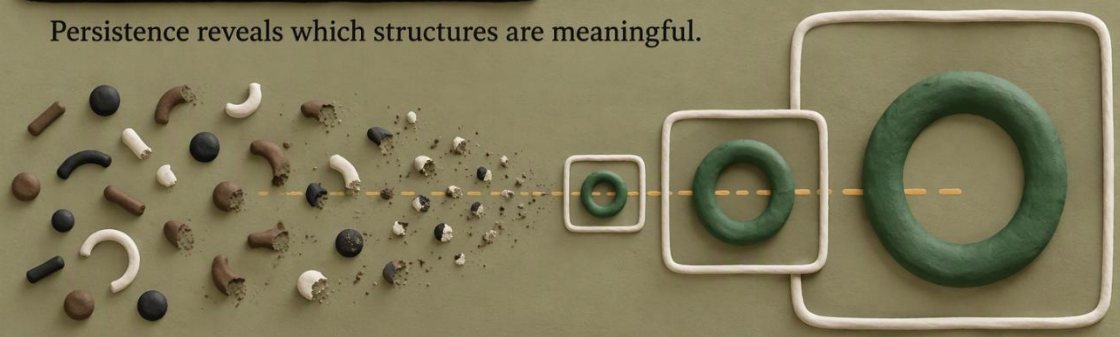

Noise can obscure the pattern—not erase it.

- The data may look messy.
- A clear empty space remains in the middle.
- TDA recognizes the underlying circular structure.

What Persists Matters

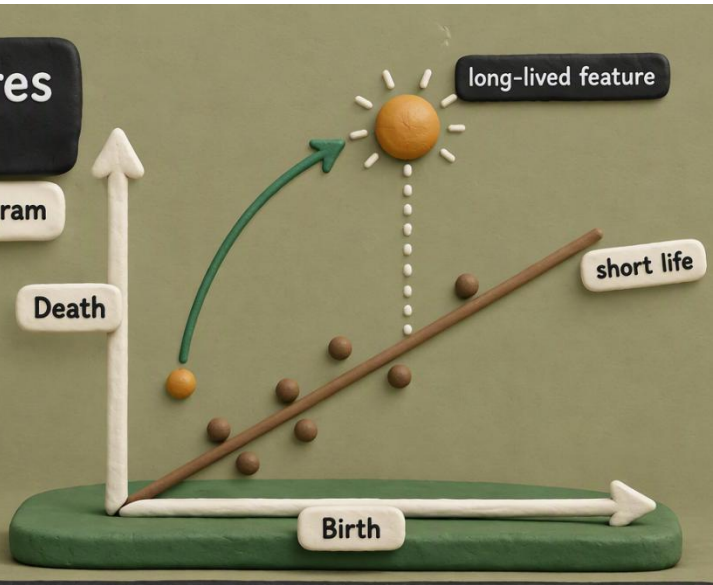

Persistence reveals which structures are meaningful.

- Random patterns appear and disappear quickly.
- Meaningful structures survive across many scales.
- Persistence helps separate signal from noise.

Tracking Features Over Time

Birth–death persistence diagram

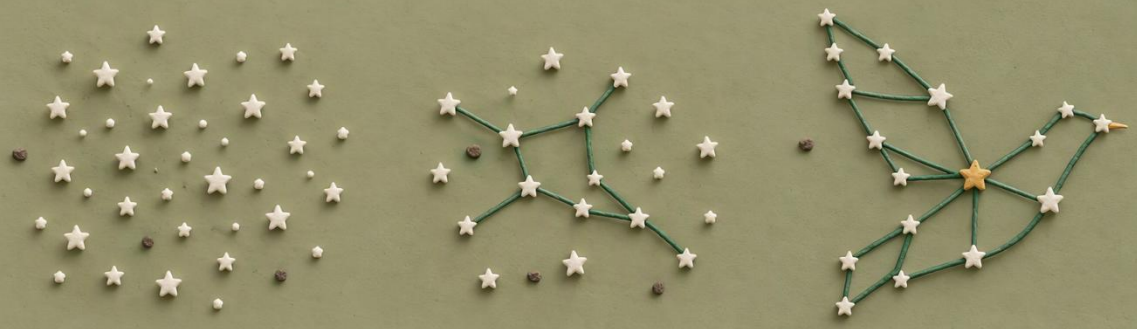

- A feature is born when it appears.
- It dies when it disappears.
- A long lifetime suggests important hidden structure.

Distance above the diagonal represents a feature's lifetime.

The Shape Was There All Along

Points → Connections → Shape → Meaning

The universe gives us points. Humans see constellations. Topological Data Analysis teaches computers to discover the constellations hidden in data.

TDA is not about finding more data.
It is about discovering the hidden shape that was already there.
